The manuscript is well revised.

However, I have a question how to estimate each daemon's influence as time. The estimation is important for accuracy of your proposed method.

For acceptance, please clarify the estimation method and its validity.

If I understand your question correctly, the proposed *cutoff* method addresses your question. We elaborate on deriving the cutoffs for each infrequent, long-running daemon from Steps 2 to 9 in Figure 3, which is marked in blue with a provided one-line comment above Step 2, for better clarification.

Here is the summary of the estimation. We first collect all the daemon processes while running PUT128 800 times enough to fit in one day.
